

Guidelines on How to Use QFN Packages and Create Associated PCB Footprints

INTRODUCTION

The Quad Fine Pitch No Leads (QFN) package is a leadless plastic package, which obtains electrical contact via lands on the bottom surface of the device. Its compact nature and low profile makes the QFN package ideal for designs where space considerations are at a premium. This small size is one of the main reasons why the QFN package is chosen for Wolfson Microelectronics devices for portable applications.

In addition to the bottom surface mounted pins, the other distinguishing feature of this package type is the exposed die paddle on the bottom side of the device. This paddle can be used to add extra strength in PCB mounting and to conduct heat more efficiently away from the die. The paddle may in future be bonded as a further analogue ground and so it is recommended that it be connected to the analogue ground of the PCB it is mounted to.

This Application note sets out to explain some of the issues related to the design of a PCB footprint for the QFN package and then goes on to describe practical considerations when soldering the device to a PCB.

PACKAGE DIMENSIONS

The first thing to consider when creating a QFN footprint is the package drawing for the device. Wolfson uses a number of different QFN packages based on JEDEC specifications as follows:

SIZE	PIN	WOLFSON TYPE
4MM×4MM	24	C
5MM×5MM	28	A
5MM×5MM	32	A AND C
6MM×6MM	40	C
7MM×7MM	48	C
9MM×9MM	64	C

Figure 1 QFN Package Range

The Wolfson QFN package currently has two types of lead termination features, these are as follows.

WOLFSON TYPE A

The Wolfson Type A package is based on the JEDEC MO-220 specification with a slight modification on the pad design. In the Type A package there is mould compound round the bottom corner of the package (see arrow). After reflow a solder fillet between the PCB and the side of the package is not required; the side of the package is not required to be solderable. This is as defined in international standard IPC-A-610D. Refer to extract in the Appendix.

Figure 2 Type A QFN Package

WOLFSON TYPE C

The Type C package is based on the JEDEC MO-220 specification with pads that are extended up the side of the package. After reflow a solder fillet between the PCB and the side of the package is not required; the side of the package is not required to be solderable. This is as defined in international standard IPC-A-610D. Refer to extract in the Appendix.

Figure 3 Type C QFN Package

The package type is dependant on the types of the part supplied and product family and can be found in the product data sheet. The dimension of the packages are, at time of document release, as follows. Please refer to the individual datasheets for the most current issue of the package dimensions.

Figure 10 64 pin 9x9 QFN Package Wolfson Type C

PCB DESIGN CONSIDERATIONS

The PCB design rules when using the QFN packages are fundamentally no different to those for other more well known packages. The most important considerations are those effects that occur during the PCB assembly process, which do affect the PCB land layout.

The most obvious difference is the presence of a large thermal die paddle on the bottom side of the device. Concern is also often shown to the pull-off strength of the QFN device when simply using the pads to fix the package. For added strength and improved thermal dissipation characteristics, the die paddle should ideally be soldered to the PCB in addition to the pins.

ROUTING OF TRACES

Traces should be routed straight out from the peripheral pads to a minimum of 500um beyond the device extremities. Traces should not be routed inwards to a via at the expense of all or part of the thermal die paddle as there would be a strong possibility of the via shorting to the die paddle. For QFN Type A packages (see Figures 5 & 6 above) traces from the corner pads should not be routed perpendicularly as there would be a strong possibility of the trace shorting to the corner tie bars. This corner area should also be free of other signal traces or copper plane areas that are connected to different ground planes than that of the die paddle. Figure 17 below, shows a good example layout where all of the above and below recommendations have been considered and adhered to.

THERMAL DISSIPATION

To allow the heat generated through this large pad to dissipate, the area under the device may require the inclusion of a thermal landing on the component side of the PCB equal in size to the maximum size of the device thermal die paddle (it is also recommended to place a thermal landing on the opposite side of the PCB) connected to analogue ground using a number of thermal vias, approximately 0.33mm (0.013 inches) diameter. These thermal vias should be completely connected (flooded over) to the thermal landing(s) (as well as internal ground planes if using a multilayer PCB) and should not be confused with "thermal relief" or "web-constructed" vias which are designed with "spokes" to decrease thermal transfer through the PCB. The number of vias will depend upon device package size, but as a guide the pitch between the vias should be between 0.74mm and 1.27mm. In Figures 11 – 15 below, 3x3 vias are used for the packages. In Figure 16, the 9X9 package's size allows an additional 8 vias. Figures 11 - 16 are not to scale for the purpose of clarity.

Figure 15 48 Pin 7x7 QFN Footprint

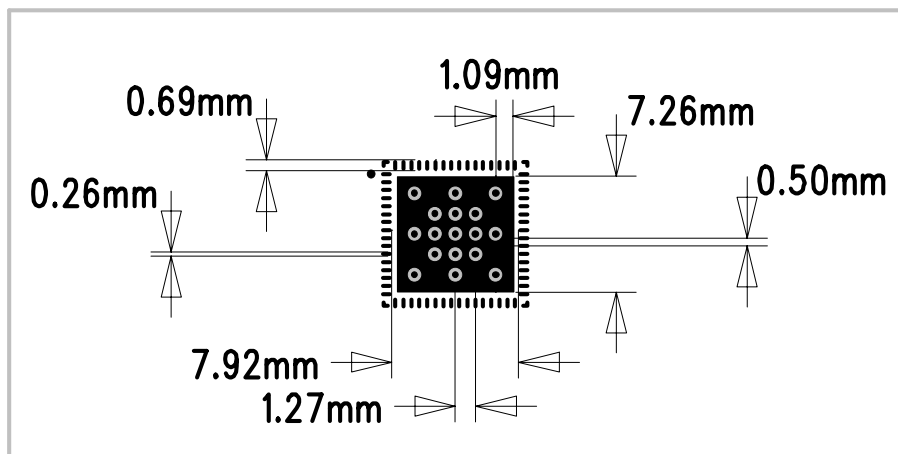

Figure 16 64 Pin 9x9 QFN Footprint

SOLDER MASK AND STENCIL DESIGN CONSIDERATIONS

The greater complexity of the QFN footprint due to the inclusion of the die paddle also means that the solder mask used during assembly will be of equal complexity. To prevent the solder of the die paddle transgressing onto the land pads during reflow, the solder mask should overlap the thermal pad outer edges by at least 100µm. This overlap will prevent transgression to the land pads even in the worst case scenario.

As per Figure 17, the vias should be left bare or untented. This minimizes the presence of voids and prevents outgassing during reflow. Additionally, if the application permits the use of plated through hole vias, then the bottom side soldermask should have a clearance around the vias equal in size to the one on the top side.

Figure 17 32 Pin 5x5 QFN Design Guide

STENCIL DESIGN FOR PERIMETER PADS

The stencil should be 1:1 or 90% of the PCB pad size and should be laser cut for accuracy and electro-polished which helps in smoothing the stencil sidewalls. The recommended stencil thickness used is 0.075mm to 0.127mm (0.003in to 0.005in) and the sidewalls of the stencil openings should be tapered approximately 5 degrees to facilitate better paste release.

DISSECTION OF THE DIE PADDLE SOLDER PASTE STENCIL

If the solder paste coverage of the thermal landing is too big, out-gassing occurs during the reflow process which may cause defects (splatter, solder balling). As per Figure 17, dividing the thermal landing into smaller screen openings reduces the risk of solder voiding and allows the solder joints for the smaller terminal pads to be at the same height as the larger ones. Figure 17 also shows how the solder paste stencil pattern can minimize the risk of the solder paste wicking down untented vias.

SOLDER PASTE RECOMMENDATIONS AND REFLOW PROFILE

Due to the size, pitch and depth of the stencil apertures for the QFN package it is recommended that type 3 no-clean solder pastes be used for printing. For reflow it is recommended an IR or Forced Convection system be used or a combination system of IR and Forced Convection. For further information on soldering, please refer to Wan_0158.

INSPECTION OF SOLDER JOINTS AFTER REFLOW

Due to the pad layout of the QFN the solder joints are formed underneath the package and are not visible. It is recommended that to ensure the joints are soldered sufficiently x-ray inspection be utilized whenever possible. Visual inspection may be used for a cursory inspection to ensure that there is no obvious solder bridging.

Shown below in Figure 18 is a typical x-ray inspection of the Wolfson 32pin QFN.

Figure 18 X-Ray Inspection of 5mm×5mm 32 pin QFN

As can be seen the solder has reflowed to form acceptable joints and there is minimal voiding in the thermal die paddle and pad solder joints, also there is no bridging visible between the joints. X-Ray inspection can also be useful in highlighting possible process problems such as solder balling and voiding which are often an indication of poorly optimized reflow profiles.

For a cursory visual inspection it should be noted that Wolfson currently provides its packages with two different QFN package types as mentioned. However it should be noted that solder fillets up the side of the QFN package are not required for acceptability of soldering; as specified in international standard IPC-A-610D; whether fillets are formed or not does not affect the mechanical strength and reliability of the solder joints. There is no difference in the mechanical strength and reliability between the two packages; the differences are only cosmetic.

IMPORTANT NOTICE

Wolfson Microelectronics plc (WM) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current. All products are sold subject to the WM terms and conditions of sale supplied at the time of order acknowledgement, including those pertaining to warranty, patent infringement, and limitation of liability.

WM warrants performance of its products to the specifications applicable at the time of sale in accordance with WM's standard warranty. Testing and other quality control techniques are utilised to the extent WM deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

In order to minimise risks associated with customer applications, adequate design and operating safeguards must be used by the customer to minimise inherent or procedural hazards. Wolfson products are not authorised for use as critical components in life support devices or systems without the express written approval of an officer of the company. Life support devices or systems are devices or systems that are intended for surgical implant into the body, or support or sustain life, and whose failure to perform when properly used in accordance with instructions for use provided, can be reasonably expected to result in a significant injury to the user. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

WM assumes no liability for applications assistance or customer product design. WM does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of WM covering or relating to any combination, machine, or process in which such products or services might be or are used. WM's publication of information regarding any third party's products or services does not constitute WM's approval, license, warranty or endorsement thereof.

Reproduction of information from the WM web site or datasheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations and notices. Representation or reproduction of this information with alteration voids all warranties provided for an associated WM product or service, is an unfair and deceptive business practice, and WM is not responsible nor liable for any such use.

Resale of WM's products or services with statements different from or beyond the parameters stated by WM for that product or service voids all express and any implied warranties for the associated WM product or service, is an unfair and deceptive business practice, and WM is not responsible nor liable for any such use.
